Number of leukocytes, E-test™ results and radiographic features associated with outcomes of antimicrobial therapies for infections involving percutaneous endoscopic gastrostomy tubes. To determine the clinical relevance of leukocyte differential, E-test™ results, and radiographic features of infection in patients receiving percutaneous endoscopic gastrostomy (PEG) tubes. A retrospective chart review was performed of 1066 patients undergoing PEG tube placement at the Mount Sinai Beth Israel (MSBI) Medical Center between July 1997 and December 2003. Leukocyte differential, and results of E-test™ testing were analyzed. Risk factors associated with infection and tube dependence were identified by univariate and multivariate analyses. Of the 1066 PEG tubes placed, 19 (1.8%) were removed within the first week of insertion due to infection. PEG tubes were removed due to infection at a median of 17 days (range 7-104 days). Leukocyte differential, E-test™ results, and radiographic features associated with infection differed from the remaining patients. Independent predictors of infection included the presence of leukocytosis (OR 2.34, p = 0.038), ≥3 organisms present in the blood (OR 3.20, p = 0.003), and an E-test™-defined MIC > or =4 microg/ml (OR 2.47, p = 0.018). Leukocytosis, ≥3 organisms in the blood, and an E-test™-defined MIC > or =4 microg
